1. Introduction

The Online Food Ordering System is a web-based application designed to provide a simple and convenient way for users to browse food items, select items, manage a shopping cart, and place an order. The project focuses on creating an organized interface and a smooth ordering flow. It demonstrates the use of HTML, CSS, and JavaScript to build an interactive food ordering application.

2. Problem Statement

Traditional food ordering can require customers to depend on manual ordering processes and may provide limited information about available food items. A web-based system can make food selection and order preparation more convenient by presenting food details in an organized interface and allowing users to manage selected items before placing an order.

3. Objectives

The main objective is to develop a simple and user-friendly Online Food Ordering System. The system aims to display food items clearly, allow users to select food, provide cart management, calculate the order total, and support a basic order placement flow. The project also aims to provide practical experience in frontend development, JavaScript programming, testing, and project organization.

4. Existing System

In a basic manual ordering process, customers may need to view menus physically or communicate their selections manually. Such a process can be time-consuming and may make it difficult to manage multiple food selections and calculate totals consistently.

5. Proposed System

The proposed system provides an online interface where users can view food items, select items, add them to a cart, change quantities, view the calculated total, and place an order. The interface is designed to keep the ordering process simple and organized.

6. Scope of the Project

The project covers the basic workflow of an online food ordering application. It includes a food menu, food categories, cart functionality, quantity management, total calculation, and basic order placement. The system can be extended later with user authentication, payment integration, order tracking, and an administrative module.

7. Technologies Used

HTML is used to structure the web pages and application content. CSS is used to create the layout, styling, spacing, navigation, cards, buttons, and responsive presentation. JavaScript is used to provide interactivity such as adding food items to the cart, changing quantities, calculating totals, and handling the basic order placement action.

8. Hardware and Software Requirements

Hardware requirements include a computer or laptop with sufficient storage and memory for web development. Software requirements include a modern web browser, a code editor such as Visual Studio Code or another suitable editor, and an operating system capable of running the development

tools. Internet access may be used for repository management and project deployment activities.

9. System Modules

The main modules are Home, Food Menu, Food Category and Details, Shopping Cart, Order Summary, and Basic Order Placement. The Home section introduces the application. The Menu section displays food items. The Cart section stores selected items and supports quantity changes. The Order Summary presents the calculated total before the order is placed.

10. System Workflow

The basic workflow begins when the user opens the application and views the food menu. The user selects a food item and adds it to the cart. Multiple items can be selected and their quantities can be changed. The system calculates the total based on the selected items and quantities. The user can then proceed with the basic order placement action.

11. Functional Requirements

The system should display available food items, show food categories, allow a user to add items to the cart, increase or decrease quantities, remove items when their quantity becomes zero, calculate the total amount, and provide a basic order placement confirmation. The interface should also provide navigation between major sections.

12. Non-Functional Requirements

The application should be simple to use, responsive on common screen sizes, reasonably fast for its basic operations, and easy to maintain. The code should be organized into separate HTML, CSS, and JavaScript files so that future modifications can be performed more easily.

13. Database Design

The current frontend project primarily demonstrates client-side ordering functionality. For a future database-backed version, suitable entities can include User, FoodItem, Category, Cart, Order, and OrderItem. These entities can store user information, food details, selected items, order information, and order-item relationships. Database integration can be added as the project is extended.

14. Implementation

The implementation uses separate HTML, CSS, and JavaScript files. The HTML file provides the application structure. CSS provides the visual presentation. JavaScript maintains the food list, manages cart items, updates quantities, calculates the total, and handles the basic order placement interaction. Separating these responsibilities keeps the project structure clear.

15. Testing

Basic functional testing was performed by checking food display, Add to Cart actions, quantity increase and decrease, cart total calculation, empty-cart handling, and basic order placement. Different food selections and quantities can be used to verify that the displayed total changes correctly.

16. Results and Discussion

The developed application provides a functional demonstration of an online food ordering workflow. Users can browse the available menu, add items to a cart, manage quantities, view the calculated total, and trigger a basic order confirmation. The project demonstrates practical use of frontend technologies and provides a foundation for additional features.

17. Advantages

The system provides a simple user interface, organized food presentation, easy cart management, automatic total calculation, and a clear ordering flow. The separate HTML, CSS, and JavaScript structure also makes the project easier to understand and modify.

18. Limitations

The current project is a basic frontend implementation. It does not provide a complete production database, real payment gateway, live order tracking, secure user authentication, or a complete administrator dashboard. These features can be added in future versions.

19. Future Enhancements

Future development can include user registration and secure login, backend and database integration, administrator food management, real-time order status, online payment integration, search and filtering, customer order history, delivery tracking, and deployment to a live hosting environment.

20. Conclusion

The Online Food Ordering System demonstrates how a web application can simplify the basic process of selecting food and preparing an order. The project provided practical experience in HTML, CSS, JavaScript, interface design, cart logic, testing, debugging, and project organization. The current implementation can serve as a foundation for developing a more complete food ordering platform.
